摘要: 以小球藻FACHB-1580和栅藻FACHB-1618为研究对象, 比较了两株绿藻在0.04% CO₂、5% CO₂和20% CO₂ (v/v)三种通气培养条件下的生长和生理特性的响应, 试图阐述与无机碳利用相关生理参数和微藻利用CO₂能力的关系。结果表明, 两株绿藻均能高效利用CO₂, 在5%(v/v)条件下均表现出最大生物量积累、最大比生长速率和最大二氧化碳固定速率。小球藻FACHB-1580和栅藻FACHB-1618最大生物量分别为3.5和5.4 g/L, 分别是0.04% CO₂ (v/v)条件的1.41和1.46倍。在高达20% CO₂ (v/v)条件下, 两株绿藻的生物量均显著高于空气组($P < 0.05$)。随着CO₂浓度的增加, 两株绿藻的无机碳亲和力、胞内和胞外CA活性、初始Rubisco活性, 及Rubisco活化度均有下降趋势, 总的Rubisco活性变化不明显。另外, 小球藻FACHB-1580存在较高的胞外和胞内CA活性; 而栅藻FACHB-1618胞外CA活性几乎为零, 胞内CA活性显著低于小球藻FACHB-1580。由此推测, 小球藻FACHB-1580能同时吸收介质中的HCO₃⁻和CO₂, 其胞内CA催化胞内HCO₃⁻快速转化为CO₂, 从而为Rubisco提供充足的CO₂来源; 而栅藻FACHB-1618主要吸收介质中的CO₂, 其胞内CA活性较低, 推测其通过提高胞内CA含量, 或增强Rubisco对CO₂的亲合力等促进光合固碳作用。

微藻是一类单细胞或简单多细胞光合自养型生物, 其数量多、分布广、生长快、繁殖周期短, 因而能高效固定CO₂并释放氧气, 平均1 kg藻细胞干重可固定1.8 kg CO₂。微藻不仅是高效固定CO₂的“工厂”, 藻体还可作为生物能源、食物、饲料、生物活性提取物等原料为人类所用^[1]。随着能源危机和环境恶化, 利用微藻减排已成为国际CO₂减排和新能源开发领域的前沿研究热点和高技术竞争点^[2]。工业排放废气中CO₂浓度往往高达10%—15%(v/v)^[3], 因此, 筛选能够有效利用高浓度CO₂的优良藻种是实现微藻减排的关键。在微藻培养过程中, CO₂供给浓度会影响培养液中无机碳的组成, 从而影响藻株对无机碳利用的机制和生长情况。研究表明, 不同藻种对CO₂的适应性不同, 如: 小球藻*Chlorella* sp.和微拟球藻*Nannochloropsis oculata*在高于5% CO₂ (v/v)条件下生长受到抑制^[4]。相反地, 莱茵衣藻*Chlamydomonas reinhardtii*在5%

CO₂ (v/v)条件下的最大比生长速率是空气组的2倍^[5]。

在自然环境下, CO₂在水中的扩散速度慢, 仅有空气中的万分之一^[6]。此时, 藻类为适应水体中的低浓度CO₂环境并保持较高的光合作用速率, 形成一种CO₂浓缩机制(CO₂ Concentrating Mechanisms, CCM)。一般而言, 微藻在低碳条件下开启CCM, 表现为K_{0.5}(DIC)显著降低^[7]。CA是CCM的重要组成部分之一, 根据其位置分布可分为胞外和胞内CA。真核藻类可能存在胞外CA, 其催化介质中HCO₃⁻与CO₂之间的快速转化, 从而保证CO₂/HCO₃⁻向胞内高效运输。嗜酸衣藻*Chlamydomonas acidophila*能够检测到胞外CA活性, 且在低碳条件下胞外CA活性显著增高^[8]。但胞外CA并不是绝对必需的, 主要与藻种相关, 如: 小球藻*Chlorella vulgaris*细胞无法检测到胞外CA活性^[9]。微藻的胞内CA主要催化胞内HCO₃⁻转化为CO₂, 从而为Rubisco供应充足的CO₂, 藻细胞胞内CA活性降低后, 尽管胞内无机碳

仍有大量积累,但是光合作用显著下降^[10]。

藻细胞吸收无机碳后,通过Calvin-Benson循环(卡尔文循环)固定CO₂,最终转化为有机物储存。1,5-二磷酸核酮糖羧化酶(D-ribulose 1,5-biphosphate carboxylase,简称为Rubisco, EC 4.1.1.39)是卡尔文循环的关键酶,它催化1分子二磷酸核酮糖(RuBP)与1分子CO₂结合产生2分子3-磷酸甘油酸(PGA)。该反应是光合固碳的限速步骤,决定着光合作用产物的积累。与一般的酶相比,Rubisco具有2个显著特征:一是非专一性,即Rubisco能同时催化羧化反应和加氧反应;二是低效性^[11],这也是藻株诱导CCM的另一个重要原因。CO₂不仅是Rubisco催化的底物,还是Rubisco的活化剂和活性调节因子^[12]。大量报道表明,CO₂浓度会影响Rubisco的特性及其蛋白的合成^[13-15],了解CO₂供给浓度对微藻Rubisco的影响,有助于更好把握微藻的生长特性。

本研究以筛选用于耦合烟道气CO₂减排的户外规模培养的潜在优良藻种为出发点,比较小球藻FACHB-1580和栅藻FACHB-1618在不同CO₂供给条件下的生长和生理响应。试图阐述与无机碳利用相关生理参数和微藻利用CO₂能力的关系,并探索有效表征微藻固定CO₂能力的生理指标,从而为高效固碳优良藻种的筛选和评价提供指导依据。

1 材料与方法

1.1 藻种来源及培养条件

实验用到的栅藻(*Scenedesmus* sp. FACHB-1618)和小球藻(*Chlorella* sp. FACHB-1580)均来自中国科学院淡水藻种库(FACHB-Collection, Wuhan, China)。

培养装置为内径5 cm,有效体积750 mL的柱状光生物反应器,培养条件为:BG11无碳培养基^[16](去除Na₂CO₃,以同等摩尔Na⁺浓度的NaCl代替),初始光照强度约为50 μmol/(m²·s),依据藻细胞密度进行调节,持续光照,温度(25±2)°C。

通气条件为0.04%、5%和20% CO₂ (v/v)三组,每组3个平行,气体流量为200 mL/min,连续通气。不同浓度CO₂由空气和纯CO₂混合而成,用CO₂测定仪(MS400, Eranntex, Shenzhen, China)测定CO₂浓度。藻液初始接种浓度为A₆₈₀=0.3±0.1,培养周期17d。

1.2 生物量测定

生物量以藻细胞干重(Dry Weight, DW)表示,接种后每2—3d取5 mL藻液,用玻璃纤维滤膜(1.2 μm,

Whatman GF/C, GE Healthcare, Chicago, IL, USA)过滤。过滤前后,滤膜在105°C, 2h烘干至恒重,称重并记录重量依次为W₀ (g), W_t (g)。相关计算公式如下:

$$\text{生物量: } X(\text{g/L})=(W_0-W_t)/5\times 1000$$

$$\text{生物量产率: } P[\text{mg}/(\text{L}\cdot\text{d})]=(X_2-X_1)/(t_2-t_1)\times 1000$$

$$\text{比生长速率: } \mu=(\lg X_2-\lg X_1)/(t_2-t_1)\times 3.332$$

$$\text{固碳速率: } R_{\text{CO}_2}=C_C\times P(M_{\text{CO}_2}/M_C)^{[1]}$$

其中, X₁和X₂分别是生长对数期的藻株在t₁和t₂时间下的干重, C_C表示微藻细胞的平均含碳量^[1], P表示生物量产率, M_{CO₂}和M_C分别表示CO₂分子和C元素的分子量。

1.3 表观无机碳亲和力常数K_{0.5}(DIC)的测定

收集对数生长期藻细胞,去上清,重悬于预备的无碳缓冲液BG11-BTP(pH 8.0)^[17]中,用该缓冲液清洗细胞3次。清洗后的细胞液取出一部分测定叶绿素;另外取出2 mL置于液相氧电极(Chlorlab2, Hansatech Instruments Ltd., Norfolk, UK)反应槽内,在饱和光强500 μmol/(m²·s)下,利用藻细胞光合固碳作用使胞内无机碳枯竭,当藻细胞光合放氧速率几乎为零时,通过微量进样器从加样孔加入不同量的NaHCO₃溶液,测定藻细胞光合放氧速率。藻株对无机碳的亲和力用无机碳半饱和常数K_{0.5} (DIC)(即光合作用速率达到一半时的无机碳浓度)来表征,并通过方程 $V=V_{\text{max}}[\text{DIC}]/(K_{0.5}+[\text{DIC}])$ 对实验数据进行非线性拟合后求得^[18]。

1.4 Rubisco活性测定

收集对数期藻液(干重约20 mg), 5000 r/min, 25°C离心5min,去上清后用pH 7.5 Tris-HCl清洗两遍。在4°C条件下,加900 μL提取液(50 mmol/L Tris-HCl pH 7.5, 1 mmol/L EDTA pH 8.0, 10 mmol/L MgCl₂, 12% (v/v) Glycerol, 1% (w/v) PVP 40, 2.5 mmol/L DTT),将细胞转移到2 mL冻存管中,并加入0.5 g玻璃珠/铅珠(直径0.5 mm);利用低温细胞破碎仪(Gene Ready, Bioer, Beijing, China)破碎细胞后,12000 r/min, 4°C离心10min,上清即Rubisco粗提液。粗提液一部分直接用于初始Rubisco活性的测定,一部分需用活化液(33 mmol/L Tris-HCl pH 7.5, 0.67 mmol/L EDTA, 33 mmol/L MgCl₂, 10 mmol/L NaHCO₃)活化后测定总的Rubisco活性^[19]。Rubisco的活化度为初始Rubisco活性与总的Rubisco活性的比值。

利用分光光度计法测定Rubisco活性^[20],并根据催化反应过程中所消耗的NADH的量来计算该酶活性^[21],测定温度均为30°C。具体方法是:取5 μL粗提液/活化酶液加入187 μL反应液(50 mmol/L

HEPES-KOH pH 8.0, 1 mmol/L EDTA pH 8.0, 20 mmol/L MgCl₂, 2.5 mmol/L DTT, 10 mmol/L NaHCO₃, 5 mmol/L ATP, 5 mmol/L Phosphocreatine, 0.2 mmol/L NADH, 10 U/mL PGK, 10 U/mL GADPH, 10 U/mL PCK)中, 最后加入8 μL 50 mmol/L RuBp, 使其终浓度达到2 mmol/L。立即测定A₃₄₀的变化, 每30s测一次, 连续10min, 计算A₃₄₀的变化率。采用氨基黑方法^[22]测定粗提液中蛋白质含量。

酶比活力: $U=10 \times \Delta A_{340} / 6.22 / 2$ (mg pro)

1.5 CA活性测定

收集对数期的藻细胞(干重约20 mg), 用20 mmol/L 巴比妥钠(CAS:144-02-5)缓冲液(pH 8.3)清洗藻细胞两遍并重悬; 重悬液直接用于胞外CA活性测定, 总的CA活性用低温细胞破碎仪(Gene Ready, Bio-er, Beijing, China)破碎细胞后测定, 胞内CA活性即总的CA与胞外CA活性的差值。

采用量电法^[23]测定CA活性。取缓冲液清洗过的细胞液测定叶绿素含量, 利用甲醇加热法^[24]提取叶绿素a。计算方法如下:

叶绿素a含量: $Chl.a$ (mg/L) = $15.56 \times A_{666} - 7.34 \times A_{653}$ ^[25]

CA酶活性: $EU=10 \times (T_0/T-1) / (\mu g Chl.a)$

T₀: 不含CA的巴比妥钠缓冲液pH从8.30降到7.30的时间(对照组);

T: 含有CA的巴比妥钠缓冲液pH从8.30降到7.30的时间(实验组)。

1.6 数据分析

实验数据采用平均值±标准差表示, 利用SPSS 18.0统计软件分析各组数据的统计学差异, 显著水平为P<0.05, 极显著水平为P<0.01。

2 结果

2.1 两株绿藻在不同浓度CO₂通气培养条件下生长的比较

两株绿藻均在5% CO₂ (v/v)条件下获得最大生物量积累、最大比生长速率和最大CO₂固定速率。经通气培养17d后, 小球藻FACHB-1580和栅藻

FACHB-1618最大生物量达到3.5和5.4 g/L(图1), 分别是空气组的1.41和1.46倍。两株绿藻最大固碳速率和最大比生长速率分别是563.7和660.9 mg/(L·d), 0.78和0.57/d(表1)。同时, 两株绿藻均能适应20% CO₂ (v/v)条件, 该条件下的比生长速率与0.04% CO₂ (v/v)组相比分别增加83%和22%, 且该条件下小球藻FACHB-1580的生物量显著高于0.04% CO₂ (v/v)组(P<0.05)。

2.2 两株绿藻在不同浓度CO₂通气培养条件下无机碳亲和力的比较

图2表示两株绿藻在饱和光强500 μmol/(m²·s)条件下的无机碳吸收曲线, 吸收曲线反应它们在不同浓度CO₂培养条件下最大光合放氧速率变化不大。但它们的表观无机碳亲和力常数K_{0.5} (DIC)均随着CO₂浓度增加而增高(图3)。小球藻FACHB-1580的K_{0.5} (DIC)分别为50.6、174.6和344.8 μmol/L, 20% CO₂ (v/v)组的K_{0.5} (DIC)是0.04% CO₂ (v/v)组的6.8倍; 栅藻FACHB-1618的K_{0.5} (DIC)分别为190.6、443.9和498.1 μmol/L, 20% CO₂ (v/v)组的K_{0.5} (DIC)是0.04% CO₂ (v/v)组的2.6倍(表2)。另外, 在同等条件下, 小球藻FACHB-1580的K_{0.5}(DIC)值

Tab. 1 Growth parameters of two strains under different CO₂ concentrations (Mean±SD)

CO ₂ 浓度CO ₂ conc.(v/v)	FACHB-1580		FACHB-1618	
	比生长速率 μ_{max} (/d)	CO ₂ 固定速率 R_{CO_2} [mg/(L·d)]	比生长速率 μ_{max} (/d)	CO ₂ 固定速率 R_{CO_2} [mg/(L·d)]
0.04% CO ₂	0.48±0.04	321.3±46.7	0.45±0.05	425.1±15.9
5% CO ₂	0.78±0.06**	563.7±40.3**	0.57±0.02*	660.9±33.7**
20% CO ₂	0.77±0.009**	521.9±33.7**	0.55±0.04*	546.9±73.9*

注: *P<0.05, **P<0.01, 下同

Note: *P<0.05, **P<0.01, the same applies below

均低于栅藻FACHB-1618, 即在同等条件下小球藻FACHB-1580的无机碳亲和力高于栅藻FACHB-1618。

2.3 两株绿藻在不同浓度CO₂通气培养条件下CA活性的比较

小球藻FACHB-1580存在胞外CA, 其活性随CO₂浓度增加显著降低; 而栅藻FACHB-1618胞外CA活性极低(≤ 3.6 EU/mg Chl.*a*), 5%和20% CO₂ (v/v)条件下几乎为零(图4)。另外, 小球藻FACHB-1580的胞内CA活性较高, 且随CO₂浓度增加其活性显著降低($P < 0.01$)。其中在0.04% CO₂ (v/v)条件下胞内CA活性为540.0 EU/(mg Chl.*a*), 是20% CO₂ (v/v)组的5.4倍。小球藻FACHB-1580高活性的胞内CA为Rubisco提供了充足的CO₂来源。相比而言,

栅藻FACHB-1618胞内CA活性较低, 随着CO₂浓度的变化, 其活性变化不明显。

2.4 两株绿藻在不同浓度CO₂通气培养条件下Rubisco活性的比较

随着CO₂浓度的增加, 两株绿藻初始Rubisco活性和Rubisco活化度均有下降趋势(图5、图6), 而总的Rubisco活性无明显变化。在0.04%、5%和20% CO₂ (v/v)下, 小球藻FACHB-1580的初始Rubisco活性分别为0.56、0.4和0.27 $\mu\text{mol CO}_2/(\text{mg pro} \cdot \text{min})$, 对应Rubisco活化度分别为43%、22%和20%; 栅藻FACHB-1618的初始Rubisco活性分别为0.68、0.58和0.49 $\mu\text{mol CO}_2/(\text{mg pro} \cdot \text{min})$, 对应Rubisco活化度分别为31%、30%和19%。20% CO₂ (v/v)条件下, 两株绿藻初始Rubisco活性及Rubisco活化度与0.04% CO₂ (v/v)组相比均显著降低($P < 0.05$)。

3 讨论

大量研究表明, 和空气条件相比, CO₂供给浓度的增加, 往往能够促进藻细胞快速生长^[26, 27]。然而, 持续高浓度CO₂的通入会迅速降低溶液pH, 可能抑制相关酶活性^[27]。大多数藻株适宜生长的CO₂浓度

范围是0.038%—10%(v/v)^[28]。小球藻(*Chlorella* sp.)只能在低于2% CO₂ (v/v)条件下生长^[4]。少数藻种,如:微拟球藻(*Nannochloropsis* sp.)在15% CO₂ (v/v)条件下比生长速率为0.52/d,相比空气条件提高58%^[26]。在本文研究中,小球藻FACHB-1580和栅藻FACHB-1618均在5% CO₂ (v/v)条件下有最大生物量积累、最大比生长速率,及最大CO₂固定速率。在20% CO₂ (v/v)条件下,它们的比生长速率与0.04% CO₂ (v/v)组相比分别增加83%和22%,表明实验所用两株绿藻均能适应体积比高达20%的CO₂供给条件并高效固定CO₂用于生物量积累。尽管栅藻FACHB-1618的生物量高于小球藻FACHB-1580,但从比生长速率来看,小球藻FACHB-1580对20% CO₂ (v/v)条件的适应性更强。

不同浓度CO₂通气培养条件下藻株的生长与其对培养液中无机碳的利用机制紧密相关。已有研究表明,微藻通常在低碳条件下开启CCM,高碳条件下CCM受抑制^[29],表现为表观无机碳亲和力常数增加,即无机碳亲和力显著下降^[30, 31]。聚球藻*Synechococcus* sp.在2% CO₂ (v/v)条件下K_{0.5}(DIC)与0.35% CO₂条件相比升高了20倍^[32];集胞藻*Synechocystis* sp.在2% CO₂ (v/v)条件下的K_{0.5}(DIC)是0.02% CO₂条件的5.4倍^[33]。在本实验中,两株绿藻的K_{0.5}(DIC)值均随CO₂供给浓度的增加而升高(图4),该结果与前人研究结果一致。

真核藻类叶绿体的存在使细胞内的分室增加,因而CCM的运行机制比蓝藻更为复杂。不同藻种的CCM运行机制不同,主要体现在无机碳泵的种类和位置,CO₂浓度提高的部位和机制以及CA的分布这三个方面^[34]。在本研究中,小球藻FACHB-1580存在胞外CA活性,而栅藻FACHB-1618胞外CA活性极低。研究表明,只有胞内CA活性的藻株,主要吸收CO₂;而胞外CA活性较高的藻株,能够同时吸收HCO₃⁻和CO₂^[35]。由此推测:栅藻FACHB-1618主要吸收介质中的CO₂,而小球藻FACHB-1580能同时吸收HCO₃⁻和CO₂。随着CO₂供给浓度的增加,小球藻FACHB-1580胞外和胞内CA活性均显著降低(P<0.01)。Swarnalatha等^[36]分离的3株淡水藻种也有相似结果,通CO₂条件下测得的胞外CA活性相比空气条件下下降77%—96%。威氏海链藻*Thalassiosira weissflogii*和三角褐指藻*Phaeodactylum tricornutum*的胞外和胞内CA活性同样在高浓度CO₂条件下降低^[37]。大量研究表明CO₂浓度升高对CA活性有明显抑制作用^[38, 39],这是因为CA在微藻利用HCO₃⁻过程中具有重要作用^[40]。由此进一步证明小球藻FACHB-1580能同时利用HCO₃⁻和CO₂;并

且随着CO₂浓度的增加, 藻株对HCO₃⁻的利用能力降低, 对CO₂的利用能力逐渐增强。

无论藻细胞从外界吸收何种形式的无机碳(HCO₃⁻或CO₂), 最终能被叶绿体内Rubisco利用的只有CO₂。关于CO₂对Rubisco的影响, 本实验结果表明: 随着CO₂供给浓度的增加, 两株绿藻总的Rubisco活性变化不明显, 而初始Rubisco活性和Rubisco活化度均有下降趋势。与0.04% CO₂ (v/v)条件相比, 20% CO₂ (v/v)条件下2株绿藻的初始Rubisco活性和Rubisco活化度均显著下降。大量关于陆生植物的研究中也表明高浓度CO₂会抑制初始Rubisco活性和活化度。如: 松树在约0.07% CO₂ (v/v)条件下初始Rubisco活性降低^[41, 42]。Sage等^[43]发现生长在0.095% CO₂ (v/v)条件下的5种植物叶片的Rubisco活化度与空气组相比全部降低。高浓度CO₂抑制初始Rubisco活性, 可能是因为在高碳条件下己糖含量增加, 通过己糖激酶途径反馈抑制Rubisco的基因表达^[44]。但是, 两株绿藻在5% CO₂ (v/v)供给条件下的初始Rubisco活性与空气组相比无显著变化(图5)。近年来, 关于大型海藻和短角毛藻的研究表明, 约0.06% CO₂ (v/v)条件下的初始Rubisco活性和空气条件相比无显著差异^[45, 46]。与空气组相比, 本研究中两株绿藻的初始Rubisco活性在5% CO₂ (v/v)供给条件下无显著变化, 但在20% CO₂ (v/v)条件下被显著抑制。根据Tcherkez等^[47]的研究, Rubisco能够根据环境的变化调整其对CO₂/O₂的特异性及对CO₂亲和力等保证最佳的光合固碳速率。可推测, 20% CO₂ (v/v)条件下两株绿藻初始Rubisco活性降低的同时, Rubisco对CO₂的亲和力有可能增加, 从而保证藻细胞高效的固碳作用。

综上, 本研究较全面地探讨了两株绿藻在不同浓度CO₂通气培养条件下的生长和生理特性的响应, 对今后藻种的筛选和评价具有一定指导意义。同时, 本研究的两株藻种均能够高效利用CO₂, 有望成为耦合烟道气减排的户外规模培养的潜在优良藻株。但是, 本研究结果还不足以形成有效地指征藻株对CO₂利用能力的评价体系。为此, 我们需要结合烟道气的特点, 进一步探讨藻株对烟道气中有毒气体(SO_x/NO_x)、粉尘等因素的耐受能力。并将实验室所选藻株在室外进行扩大培养, 得到更多藻株户外大规模培养的生长、生理参数等。

Abstract: Selection of microalgae strains that are capable of utilizing high concentration of CO₂ is essential for industrial application. At present, the microalgae research mainly focus on the biomass, bioactive products and recovery properties, rather than physiological properties. The influence of different CO₂ concentrations, including air, 5% CO₂ and 20% CO₂ (v/v), on the growth and physiological properties of *Chlorella* sp. FACHB-1580 and *Scenedesmus* sp. FACHB-1618 were studied. The goal was to clarify the relationship between the physiological properties and the CO₂ utilizing capacity. Results showed that both strains were capable to use high concentration of CO₂ and had the maximum biomass accumulation, specific growth rate and CO₂ fixation rate under 5% CO₂ (v/v) culture condition. The maximum biomass was 3.5 g/L in *Chlorella* sp. FACHB-1580 and 5.4 g/L in *Scenedesmus* sp. FACHB-1618 which was 1.41 and 1.46 times higher in comparison with the control (air) group, respectively. Both strains had higher biomass under 20% CO₂ (v/v) condition than that in the air group ($P < 0.05$). With the increasing supply of CO₂, the affinity of inorganic carbon, the activity of intracellular (CA_{int}) and extracellular (CA_{ext}) carbonic anhydrase, as well as the initial activity and activation rate of Rubisco declined in both strains. However, there was no significant difference in the total Rubisco activity across time. In addition, *Chlorella* sp. FACHB-1580 had significantly higher levels of CA_{int} and CA_{ext} activities. By contrast, *Scenedesmus* sp. FACHB-1618 had very poor CA_{int} and CA_{ext} activities and were not detectable, indicating these two strains differed significantly in the utility of inorganic carbon. It was speculated that *Chlorella* sp. FACHB-1580 can absorb both CO₂ and HCO₃⁻ whereas the *Scenedesmus* sp. FACHB-1618 tends to only absorb CO₂. *Chlorella* sp. FACHB-1580 may obtain its abundant CO₂ for Rubisco via high CA_{int} activity; for *Scenedesmus* sp. FACHB-1618, due to its lower CA_{int} activity, it may increase the amount of CA protein, or higher carboxylase affinity for CO₂ to promote the reactions of photosynthesis.

Key words: Green algae; Biomass; CO₂ concentrating mechanisms; Carbonic anhydrase; Ribulose-1, 5-bisphosphate carboxylase (Rubisco)
